Epidemiology

More than 95% of adults (aged >20 years) born in the United States have immunity to varicella-zoster virus (VZV), mostly due to primary VZV infection, known as varicella (or chickenpox). A varicella vaccine became available in the United States in 1995; most children born in the United States after 2005 are immune to varicella as a result of vaccination. Reactivation of latent VZV results in herpes zoster (shingles). In the general population, the incidence of herpes zoster is about 3.6 cases per 1,000 person-years, with much higher incidence seen among elderly and immunocompromised individuals. Before the availability of antiretroviral therapy (ART), the incidence of herpes zoster was more than 15-fold higher among adults with HIV than among age-matched controls without HIV. Herpes zoster can occur in adults with HIV at any CD4 T lymphocyte (CD4) cell count, but the risk of disease is higher with CD4 counts <200 cells/mm³. In addition, HIV viremia is associated with an increased risk for incident herpes zoster. ART has been shown to reduce the incidence of herpes zoster in adults with HIV, presumably because of immune restoration, although the risk of herpes zoster remains three-fold higher in adults with HIV than in the general population. Several studies have demonstrated that the risk of herpes zoster in adults with HIV is increased in the 6-month period immediately after initiation of ART, possibly because of an immune reconstitution inflammatory syndrome (IRIS)-related mechanism.

Clinical Manifestations

Varicella rash tends to have a central distribution with lesions first appearing on the head, then the trunk, and finally the extremities, evolving through stages of macules, papules, vesicles, pustules, and crusts. The rash is characterized by rapid evolution of lesions during the initial 8 to 12 hours after onset, by successive crops of new lesions, and by the presence of lesions in different stages of development. New vesicle formation continues for 2 days to 4 days, accompanied by pruritus, fever, headache, malaise, and anorexia. Primary varicella can cause substantial morbidity in adolescents and adults with HIV. Visceral dissemination, especially VZV pneumonitis, is well documented. Because most adults with HIV in the United States are VZV seropositive, primary varicella is an uncommon occurrence in this population.

Herpes zoster manifests as a painful cutaneous eruption in a dermatomal distribution, often preceded by prodromal pain. The most common sites for herpes zoster are the thoracic dermatomes (40% to 50% of cases), followed by cranial nerve (20% to 25%), cervical (15% to 20%), lumbar (15%), and sacral (5%) dermatomes. Skin changes begin with an erythematous maculopapular rash, followed by the appearance of clear vesicles and accompanied by pain, which may be severe. New vesicle formation typically continues for 3 to 5 days, followed by lesion pustulation and scabbing. Crusts typically persist for 2 to 3 weeks. About 20% to 30% of patients with HIV have one or more subsequent episodes of herpes zoster, which may involve the same or different dermatomes. The probability of a recurrence of herpes zoster within 1 year of the index episode is approximately 10%. Approximately 10% to 15% of patients with HIV report post-herpetic neuralgia as a complication following herpes zoster.

When herpes zoster involves the nasociliary branch of the trigeminal nerve, the eye can be affected (herpes zoster ophthalmicus [HZO]), resulting in keratitis (inflammation of the cornea) or anterior uveitis (inflammation of the iris and anterior ciliary body) or both. Vesicles on the tip of the nose (Hutchinson sign) are a clue that the nasociliary branch is involved. With corneal involvement, there may be an initial brief period during which the corneal epithelium is infected with VZV, but the major problem is inflammation of the corneal stroma, which can result in scarring, neovascularization, or necrosis, with loss of vision. Stromal keratitis can be chronic. Once it occurs, VZV-associated anterior uveitis also tends to be chronic and can result in increased intraocular pressure or glaucoma, scarring of intraocular tissues, and cataract.

Stromal keratitis and anterior uveitis may not develop immediately after the appearance of skin vesicles on
the forehead and scalp. Therefore, patients with normal eye examinations initially should receive follow-up eye examinations, even after the skin lesions heal. Antiviral treatment of herpes zoster at the onset of cutaneous lesions reduces the incidence and severity of ophthalmic involvement.

Some patients with HZO may develop late dendriform lesions of the corneal epithelium that contain virus and will respond rapidly to systemic or topical anti-herpetic medications. These lesions are usually painful. In one study, the median time from onset of HZO to development of late dendriform lesions was 5 months, and the risk of recurrences decreased over time. The frequency with which these late infectious lesions occur has not been determined.

Acute retinal necrosis (ARN) and progressive outer retinal necrosis (PORN) are variants of necrotizing retinopathy caused by VZV. Although ARN can occur in both immunocompetent and immunocompromised patients, PORN occurs almost exclusively in patients with AIDS with CD4 counts <100 cells/mm³. In contrast to ARN, PORN is characterized by minimal inflammation in the aqueous and vitreous humor, absence of occlusive retinal vasculitis, and multiple discrete peripheral lesions that manifest initially as yellow foci of retinal opacification in the outer retinal layers. PORN lesions rapidly coalesce, causing full-thickness retinal necrosis and subsequent retinal detachment. Both ARN and PORN are associated with high rates of loss of vision.

Patients with HIV who have CD4 counts <200 cells/mm³ are at highest risk of herpes zoster-related complications, including disseminated herpes zoster. The central nervous system (CNS) is a target organ for herpes zoster dissemination in patients who also have HIV. Various VZV-related neurologic syndromes occur in patients with HIV, including CNS vasculitis, multifocal leukoencephalitis, ventriculitis, myelitis and myeloradiculitis, optic neuritis, cranial nerve palsies and focal brain-stem lesions, and aseptic meningitis.

**Diagnosis**

Varicella and herpes zoster are typically distinctive in appearance and can usually be clinically diagnosed. Varicella can also be diagnosed retrospectively by documenting seroconversion (i.e., immunoglobulin G [IgG] antibody negative to positive). In immunocompromised persons, varicella may be difficult to distinguish from disseminated herpes zoster (as opposed to dermatomal herpes zoster); a history of VZV exposure, a rash that began with a dermatomal pattern, and VZV serologic testing to assess prior VZV infection may be helpful to distinguish disseminated herpes zoster from varicella. When lesions are atypical or difficult to distinguish from those due to other potential etiologies (including herpes simplex virus [HSV]), swabs of vesicular fluid from a fresh lesion or tissue biopsies can be submitted for viral culture, direct fluorescent antigen testing, or polymerase chain reaction (PCR). Additionally, scabs may be adequate specimens for PCR testing. PCR of lesions is the most sensitive and specific method for diagnosis of VZV infections. Histopathology and PCR (of blood or fluids such as cerebrospinal fluid or vitreous humor) can aid with diagnosis of VZV infections of visceral organs (e.g., pneumonitis, encephalitis, retinitis).

**Preventing Exposure**

Persons with HIV who are susceptible to VZV (i.e., persons who have no history of chickenpox or shingles, who are seronegative for VZV, and who have no history of vaccination against VZV) should avoid exposure to individuals with varicella or herpes zoster (CIII).

Household contacts of persons with HIV without evidence of immunity to VZV should be vaccinated to prevent acquisition of varicella and potential transmission of wild-type VZV to susceptible contacts with HIV (BIII).

**Preventing Disease**

*Vaccination to Prevent Primary Infection (Varicella)*

The live attenuated varicella vaccine (Varivax®) has been documented to be safe and immunogenic in children with HIV who have relatively preserved immune systems (CD4 percentage ≥15%) and is recommended...

*Guidelines for the Prevention and Treatment of Opportunistic Infections in Adults and Adolescents with HIV*
for this population of children with HIV. Varicella vaccination of children with HIV also reduces the risk of subsequent herpes zoster. Varicella-seronegative adults are potential candidates for varicella vaccination. Some experts would serologically screen adults with HIV without a history of prior varicella or varicella vaccination for VZV IgG. However, the value of this approach may be limited by the lack of sensitivity of commercially available VZV antibody assays (particularly for vaccine-induced antibody). No studies have evaluated the vaccine in adolescents or adults with HIV, but many experts recommend varicella vaccination (2 doses, administered 3 months apart) for VZV-susceptible persons with HIV aged ≥8 years with CD4 counts ≥200 cells/mm$^3$ (BIII). If varicella vaccination results in disease caused by vaccine virus (a rare event), therapy with acyclovir is recommended (AIII). Administration of varicella vaccine to more severely immunocompromised patients with HIV (CD4 counts <200 cells/mm$^3$) is contraindicated (AIII). Given the high prevalence of VZV seropositivity in adults, administration of varicella vaccine for adults will be infrequent. If post-exposure varicella-zoster immune globulin (VariZIG™) has been administered, an interval of ≥5 months is recommended before varicella vaccination (CIII). If post-exposure acyclovir has been administered, an interval of ≥3 days is recommended before varicella vaccination (CIII).
**Vaccination to Prevent Reactivation Disease (Herpes Zoster)**

Two Food and Drug Administration (FDA)-approved vaccines are currently available for the prevention of herpes zoster in immunocompetent adults. In 2017, a subunit vaccine containing recombinant VZV glycoprotein E (gE) and adjuvant AS01B (recombinant zoster vaccine, RZV, Shingrix) was FDA-approved and recommended by the Advisory Committee on Immunization Practices (ACIP) to prevent herpes zoster in immunocompetent adults aged ≥50 years, given on a 2-dose schedule. The approval and recommendation for the vaccine were based on pivotal Phase 3 randomized, placebo-controlled clinical trials involving >30,000 participants in which the vaccine efficacy against herpes zoster in vaccinated participants was 97.2% overall and 91.3% in those aged ≥70 years. The most common solicited adverse reactions in vaccine recipients were pain (78% of recipients), myalgia (45%), and fatigue (45%), with grade 3 injection site reactions (pain, redness, and swelling) reported in 9.4% of vaccine recipients and grade 3 solicited systemic events (myalgia, fatigue, headache, fever, and gastrointestinal symptoms) reported by 10.8% of vaccine recipients. Systemic grade 3 reactions were reported more frequently after Dose 2 than after Dose 1.

There are limited data on use of RZV in persons with HIV, and to date ACIP has not recommended the use of RZV in persons with HIV. A Phase 1/2 randomized, placebo-controlled study enrolled 94 adults with HIV receiving ART with CD4 count ≥200 cells/mm³, 14 adults receiving ART with CD4 count <200 cells/mm³, and 15 ART-naive adults with CD4 count ≥500 cells/mm³. The participants’ median age was 46 years. Participants received the vaccine in three doses administered at 0, 2, and 6 months. The vaccine increased humoral and cell-mediated immunity to VZV gE, after two doses, including among persons with CD4 counts<200 cells/mm³. The most common side effects included pain at the injection sites (98.6% of participants, 16.4% grade 3), fatigue (75.3%, 16.4% grade 3), myalgia (74.0%, 13.7% grade 3) and headache (64.4%, 8.2% grade 3). No vaccine-related severe adverse events occurred during follow-up. Based on these very limited data in persons with HIV, the vaccine appears safe and immunogenic. There are no efficacy data available for the RZV among persons with HIV.

Given that that risk of herpes zoster is high among persons with HIV, and the vaccine appears safe, experts recommend administration of RZV to persons with HIV aged ≥50 years following the FDA-approved schedule for persons without HIV (IM dose at 0 and 2 months) (AIII).

There are no data regarding the optimal timing of vaccination for persons who have CD4 counts <200 cells/mm³ or who are not virologically suppressed on ART. Following initiation of ART, some experts would administer the RZV vaccination series after CD4 count recovery (CIII), and others would administer the series after virologic suppression was achieved (CIII). There are no efficacy data to guide RZV vaccination in persons with HIV aged <50 years given that

- There is limited clinical trial experience demonstrating safety in immunocompetent persons <50 years, and
- The duration of protection is not known.

Thus, at this time, RZV is not recommended for persons aged <50 years with HIV infection. RZV is not a treatment for herpes zoster and should not be given during acute episodes (AIII) and should not be given to individuals with VZV-related inflammatory eye disease (keratitis or anterior uveitis) during episodes of active inflammation (AIII).

A one-dose attenuated live-zoster virus vaccine (zoster vaccine live, ZVL, Zostavax®) for prevention of herpes zoster is FDA-approved for use in immunocompetent adults aged ≥50 years. In Phase 3 clinical trials, the vaccine had 70% efficacy at preventing herpes zoster among adults aged 50 to 59 years, but efficacy declined with age, to 38% among those aged ≥70 years. Given the higher efficacy for RZV, ACIP narrowly recommended RZV rather than ZVL in adults aged ≥50 years without HIV. A randomized, double-blind, placebo-controlled trial of a 2-dose regimen of ZVL (administered at Day 0 and Week 6) was conducted in 395 persons with HIV who were virologically suppressed on ART and had CD4 count ≥200 cells/mm³. At 12 weeks post vaccination, VZV antibody titers and cell-mediated immunity increased among vaccine recipients. Injection site reactions were common (42% of vaccine recipients). No vaccine-strain herpes zoster cases were detected. Based on these data, ZVL appears to be safe and immunogenic in persons with HIV and CD4 count.
≥200 cells/mm³. An observational study followed 38 patients with HIV aged ≥50 years with CD4 count ≥350 cell/mm³ who received a single dose of ZVL and showed 2 patients (5%) had grade 3 or 4 adverse events; one patient with injection site pain, and one with grade 3 pruritis. Herpes zoster was diagnosed in one patient (3%) within 1 year after the vaccine was administered.47 Vaccine efficacy of ZVL in patients with HIV is not known.

Given the higher efficacy of RZV among immunocompetent patients, experts prefer RZV over ZVL in persons with HIV aged ≥50 years (AIII). However, if RZV is not available or cannot be given because of an allergy or intolerance, ZVL can be given to prevent herpes zoster in patients with HIV and CD4 count>200 cells/mm³ (BIII).

Importantly, ZVL vaccine is contraindicated in persons with HIV with CD4 counts<200 cells/mm³ given concerns about the potential for disseminated ZVL vaccine strain infection (AIII).

**Treating Disease**

**Varicella**

No controlled prospective studies of antiviral therapy for varicella in adults with HIV have been reported. For uncomplicated varicella, the preferred treatment options are valacyclovir (1 g PO three times daily), or famciclovir (500 mg PO three times daily), initiated as early as possible after lesion onset and continued for 5 to 7 days (AII). Oral acyclovir (20 mg/kg body weight up to a maximum dose of 800 mg five times daily) is an alternative (BII). Intravenous (IV) acyclovir 10 mg/kg every 8 hours for 7 to 10 days is the recommended initial treatment for patients with HIV with severe or complicated varicella (AIII). If no evidence of visceral involvement with VZV is apparent, many experts recommend switching from IV to oral antiviral therapy after the patient has defervesced (BIII).50

**Herpes Zoster**

Antiviral therapy should be instituted as soon as possible for all patients with HIV with herpes zoster diagnosed within 1 week of rash onset (or any time prior to full crusting of lesions). The recommended treatment options for acute localized dermatomal herpes zoster in patients with HIV are oral valacyclovir (AII), famciclovir (AII), or acyclovir (BII) (doses as above) for 7 to 10 days, although longer durations of therapy should be considered when lesions resolve slowly. Valacyclovir or famciclovir are preferred because of their improved pharmacokinetic properties and simplified dosing schedule. If cutaneous lesions are extensive or if visceral involvement is suspected, IV acyclovir should be initiated and continued until clinical improvement is evident (AII). A switch from IV acyclovir to oral antiviral therapy (to complete a 10- to 14-day treatment course) is reasonable when formation of new cutaneous lesions has ceased, and the signs and symptoms of visceral VZV infection are improving (BIII). Adjunctive corticosteroid therapy for herpes zoster in people with HIV is not recommended because there is no data supporting its benefit in this population (AIII).

In patients with HZO, both stromal keratitis and anterior uveitis require treatment with topical corticosteroids; in many cases, chronic, low-dose topical corticosteroid therapy is necessary to maintain suppression of inflammation. Recurrences or exacerbations of inflammation are common. A role for antiviral agents in the management of chronic keratitis and uveitis has not been established.

ARN should be treated promptly with antiviral therapy. One treatment recommended by some experts is high-dose IV acyclovir (10 mg/kg every 8 hours for 10 to 14 days), followed by prolonged high-dose oral valacyclovir (1 g three times daily) (AIII). High-dose oral antiviral treatment for ≥14 weeks has been shown to decrease the risk of second eye involvement among those who present with unilateral ARN syndrome; however, many ophthalmologists and infectious disease specialists will continue oral antiviral therapy for much longer. Many experts would also include one or two doses of intravitreal ganciclovir as part of the initial induction therapy (BIII). Use of oral valaciclovir instead of IV acyclovir for initial treatment has been reported. This approach should be used with caution, as serum drug levels with oral treatment will not be as high as those achieved with IV administration (CIII). Involvement of an experienced ophthalmologist in management of patients with VZV ocular disease is strongly recommended (AIII).
Optimal antiviral therapy for PORN remains undefined and should be managed in consultation with an experienced ophthalmologist (AIII). Outcomes with IV acyclovir or ganciclovir monotherapy were poor. Better results were obtained with IV ganciclovir (or the combination of ganciclovir plus foscarnet), along with intravitreal antiviral drug injections (AIII) coupled with injections of at least one intravitreal drug (ganciclovir or foscarnet) (BIII). Intravitreal cidofovir should not be used because such injections may be associated with loss of intraocular pressure and other adverse effects. Ganciclovir ocular implants previously recommended by some experts are no longer manufactured. The prognosis for visual preservation in involved eyes is poor, despite aggressive antiviral therapy.

**When to Start Antiretroviral Therapy**

All persons with HIV should receive ART as soon as possible after diagnosis of HIV infection. The presence of disease caused by VZV is not an indication to defer or discontinue ART (AIII).

**Monitoring of Response to Therapy and Adverse Events (Including IRIS)**

For monitoring and adverse event recommendations related to anti-herpesvirus drugs, see preceding guideline sections on herpes simplex virus and cytomegalovirus.

Initiation of ART appears to be associated with an increased frequency of VZV reactivation, peaking at about 3 months after ART initiation. Observational studies have shown the risk of herpes zoster to increase two- to four-fold between 4 and 16 weeks after initiating ART. The clinical presentation and natural history of herpes zoster in the setting of immune reconstitution is similar to that observed in other patients with HIV, and episodes of herpes zoster in either setting should be managed in the same manner.

**Managing Treatment Failure**

Treatment failure caused by resistance of VZV to acyclovir and related drugs (e.g., famciclovir, ganciclovir) is rare, but should be suspected when clinical findings do not improve within 7 days of initiation of therapy or when skin lesions have an atypical (e.g., verrucous) appearance. A viral culture should be obtained, and if VZV is isolated, susceptibility testing performed to establish antiviral drug susceptibility and to document the need for alternative therapy. Among patients with suspected or proven acyclovir-resistant VZV infections, treatment with IV foscarnet is recommended (AII). IV cidofovir is a potential alternative (CIII). Both foscarnet and cidofovir are nephrotoxic agents and should be given in consultation with an expert in infectious diseases.

**Special Considerations During Pregnancy**

Pregnant women with HIV who are susceptible to VZV and are in close contact with a person with active varicella or herpes zoster should receive VariZIG as soon as possible (within 10 days) after exposure to VZV (AIII). If oral acyclovir is used for post-exposure prophylaxis, VZV serology should be performed so that the drug can be discontinued if the patient is seropositive for VZV (CIII). Pregnant women **should not receive** varicella vaccine (AIII).

For pregnant women without HIV with varicella, the risk of transmitting VZV to the infant resulting in congenital varicella syndrome is 0.4% when varicella infection occurs at or before 12 weeks’ gestation, 2.2% with infection at 13 to 20 weeks, and negligible with infection after 20 weeks. Women with varicella during the first half of pregnancy should be counseled about the risks to the fetus and offered detailed ultrasound surveillance for findings indicative of fetal congenital varicella syndrome. Administration of VariZIG is recommended primarily to prevent complications in the mother; whether it has any benefit in prevention of congenital varicella syndrome is unknown. VariZIG should be administered to infants born to women who have varicella from 5 days before to 2 days after delivery to reduce the severity and mortality of neonatal varicella acquired by exposure to maternal viremia (AIII).

Oral acyclovir or valacyclovir are the preferred treatments for pregnant women with HIV who have uncomplicated varicella during pregnancy (BIII). Pregnant women with HIV who have severe varicella or...
who exhibit signs or symptoms of VZV pneumonitis should be hospitalized and treated with IV acyclovir (10 mg/kg every 8 hours) (AII).

No controlled studies of antiviral therapy of herpes zoster during pregnancy have been reported. Recommended therapy for uncomplicated herpes zoster in pregnant women with HIV is oral acyclovir or valacyclovir (BIII). Pregnant women should not receive the herpes zoster vaccine (AIII).

Recommendations for Preventing and Treating Varicella-Zoster Virus Infections

Pre-Exposure Prevention of VZV Primary Infection

Indications:
• Adults and adolescents with HIV who have CD4 counts ≥200 cells/mm³ and who do not have documentation of varicella vaccination, a history or diagnosis of varicella or herpes zoster confirmed by a health care provider, or laboratory confirmation of VZV disease; and anyone with HIV who is VZV seronegative should avoid exposure to persons with varicella or herpes zoster (CIII).

Vaccination:
• VZV-susceptible household contacts of VZV-susceptible persons with HIV should be vaccinated to prevent potential transmission of VZV to their contacts with HIV (BII).
• In VZV-seronegative persons with CD4 counts ≥200 cells/mm³, primary varicella vaccination (Varivax™), 2 doses (0.5 mL SQ) administered 3 months apart (CIII).
• If vaccination results in disease due to live-attenuated vaccine virus, treatment with acyclovir is recommended (AIII).
• If post-exposure VarizIG has been administered, wait ≥5 months before varicella vaccination (CIII).
• If post-exposure acyclovir has been administered, wait ≥3 days before varicella vaccination (CIII).
• Administration of varicella vaccine to severely immunocompromised patients with HIV (CD4 counts <200 cells/mm³) is contraindicated (AIII).

Post-Exposure Prophylaxis of VZV Primary Infection

Indication (AIII):
• Close contact with a person who has active varicella or herpes zoster, and
• Susceptible to VZV (i.e., no history of varicella vaccination, no history of varicella or herpes zoster, or known to be VZV seronegative)

Preferred Prophylaxis:
• VarizIG™ 125 IU/10 kg (maximum of 625 IU) IM, administered as soon as possible and within 10 days after exposure to a person with active varicella or herpes zoster (AII).
• VarizIG can be obtained by contacting FFF Enterprises (Temecula, California) at (800) 843-7477 or ASD Healthcare (Frisco, Texas) at (800) 746-6273. If post-exposure VarizIG has been administered, wait ≥5 months before varicella vaccination (CIII).

Note: Patients receiving monthly high dose IVIG (i.e., >400 mg/kg) are likely protected against VZV and probably do not require VarizIG if the last dose of IVIG they received was administered <3 weeks before VZV exposure.

Alternative Prophylaxis (Begin 7–10 Days After Exposure):
• Acyclovir 800 mg PO 5 times a day for 5–7 days (BII), or
• Valacyclovir 1 g PO three times a day for 5–7 days (BII)

Note: Neither these pre-emptive interventions nor post-exposure varicella vaccination have been studied in adults and adolescents with HIV. If acyclovir or valacyclovir is used, varicella vaccines should not be given <72 hours after the last dose of the antiviral drug.

Preventing Herpes Zoster (Shingles)

Vaccination:
• RZV (Shingrix) is preferred over attenuated ZVL (Zostavax) for prevention of herpes zoster (AIII).

RZV:
• Recommended in adults with HIV aged ≥50 years, regardless of CD4 count
• RZV 0.5 mL IM injection (2 dose series) at 0 and then at 2 to 6 months (AIII).
• RZV should not be given during an acute episode of herpes zoster (AIII).
• Following initiation of ART, some experts would delay RZV vaccination until patients are virologically suppressed on ART (CIII) or until CD4 count recovery (CIII) to maximize immunologic response to the vaccine.

Attenuated ZVL:
• If RZV is not available or cannot be given because of allergy or intolerance, ZVL can be administered (0.65 mL SQ for 1 dose) (BII).
• ZVL is contraindicated for persons with CD4 count<200 cells/mm³ (AIII).
Recommendations for Preventing and Treating Varicella Zoster Virus Infections

Treating Varicella Infections

Primary Varicella Infection (Chickenpox)

Uncomplicated Cases

Preferred Therapy:

- Valacyclovir 1 g PO three times a day (AII), or
- Famciclovir 500 mg PO three times a day (AII)

Alternative Therapy:

- Acyclovir 800 mg PO 5 times daily (BII)

Duration:

- 5–7 days

Severe or Complicated Cases:

- Acyclovir 10 mg/kg IV every 8 hours for 7–10 days (AIII)
- May switch to oral famciclovir, valacyclovir, or acyclovir after defervescence if there is no evidence of visceral involvement (BIII)

Herpes Zoster (Shingles)

Acute, Localized, Dermatomal

Preferred Therapy:

- Valacyclovir 1,000 mg PO three times a day (AII), or
- Famciclovir 500 mg PO three times a day (AII)

Alternative Therapy:

- Acyclovir 800 mg PO 5 times a day (BII)

Duration:

- 7–10 days; longer duration should be considered if lesions resolve slowly

HZO:

- Late dendriform lesions of the corneal epithelium should be treated with systemic or topical anti-herpetic medications (AIII).

Extensive Cutaneous Lesion or Visceral Involvement:

- Acyclovir 10 mg/kg IV every 8 hours until clinical improvement is evident (AII).
- Switch to oral therapy (valacyclovir 1 g three times a day, famciclovir 500 mg three times a day, or acyclovir 800 mg PO five times a day to complete a 10-day to 14-day course) when formation of new lesions has ceased and signs and symptoms of visceral VZV infection are improving (BIII).

ARN:

- Acyclovir 10 mg/kg IV every 8 hours for 10–14 days, followed by valacyclovir 1 g PO three times a day for ≥14 weeks (AIII) plus ganciclovir 2 mg/0.05 mL intravitreal twice weekly for 1–2 doses (BIII).
- Involvement of an experienced ophthalmologist is strongly recommended (AIII).
- Use of oral valaciclovir instead of IV acyclovir for initial treatment has been reported, but this approach should be used with caution, as serum drug levels with oral treatment will not be as high as those achieved with IV administration (CIII).

PORN:

- Involvement of an experienced ophthalmologist is strongly recommended (AIII).
- Acyclovir 10 mg/kg IV every 8 hours or ganciclovir 5 mg/kg every 12 hours plus ganciclovir 2 mg/0.05 mL and/or foscarnet 1.2 mg/0.05 mL intravitreal twice weekly (AIII)
- Optimize ART regimen (AIII)
- Duration of therapy is not well defined and should be determined based on clinical, virologic, and immunologic responses in consultation with an ophthalmologist.

Note: Ganciclovir ocular implants are no longer commercially available.

Key: ARN = acute retinal necrosis; ART = antiretroviral therapy; CD4 = CD4 T lymphocyte cell; HZO = herpes zoster ophthalmicus; IM = intramuscular; IU = international unit; IV = intravenous; IVIG = intravenous immunoglobulin; PO = orally; PORN = progressive outer retinal necrosis; RZV = recombinant zoster vaccine; SQ = subcutaneous; VarIZIG = varicella zoster immune globulin; VZV = varicella zoster virus; ZVL = zoster vaccine live
