| Dyslipidemia    | PIs:            | Onset: As early as 2 weeks to months after beginning therapy. | Reported frequency varies with specific ARV regimen, duration of ART, and specific medication used to diagnose lipid abnormalities. | Advanced-stage HIV disease, High-fat, high-cholesterol diet, Lack of exercise, Obesity, Hypertension, Smoking, Family history of dyslipidemia or premature ASCVD, Metabolic syndrome, Fat maldistribution. | Prevention: Low-fat diet, Exercise, Smoking-prevention counseling, When possible, use ARVs associated with a lower prevalence of dyslipidemia. These include INSTIs and newer PIs (e.g., ATV, DRV). | Assess all patients for additional ASCVD risk factors. Patients with HIV are considered to be at moderate risk of ASCVD. ARV regimen changes should be considered, especially when the patient is receiving older PIs (e.g., LPV/r) and/or RTV boosting. Switching to a PI-sparing regimen, a PI-based regimen with a more favorable lipid profile, or Cobi boosting causes a decline in LDL-C or TG values. However, the lipid-lowering effect for LDL-C is less pronounced than with statin therapy. Refer patients to a lipid specialist early if LDL-C ≥250 mg/dL or TG is ≥500 mg/dL. If LDL-C is ≥130 mg/dL but <250 mg, or TG is ≥150 mg/dL but <500 mg/dL, the following staged treatment approach is recommended by the NHLBI guidelines:

- Implement diet, nutrition, and lifestyle management for 6–9 months. Consult with a dietician if one is available.
- If a 6-month to 9-month trial of lifestyle modification fails and the patient is aged ≥10 years, consider implementing lipid-lowering therapy after consulting a lipid specialist.
- Statin therapy should be considered for patients with elevated LDL-C levels. NHLBI provides recommendations for statin therapy in patients with specific LDL-C levels and risk factors. |

### Prevention

- Assess all patients for additional ASCVD risk factors. Patients with HIV are considered to be at moderate risk of ASCVD. ARV regimen changes should be considered, especially when the patient is receiving older PIs (e.g., LPV/r) and/or RTV boosting. Switching to a PI-sparing regimen, a PI-based regimen with a more favorable lipid profile, or Cobi boosting causes a decline in LDL-C or TG values. However, the lipid-lowering effect for LDL-C is less pronounced than with statin therapy. Refer patients to a lipid specialist early if LDL-C ≥250 mg/dL or TG is ≥500 mg/dL. If LDL-C is ≥130 mg/dL but <250 mg, or TG is ≥150 mg/dL but <500 mg/dL, the following staged treatment approach is recommended by the NHLBI guidelines:

  - Implement diet, nutrition, and lifestyle management for 6–9 months. Consult with a dietician if one is available.
  - If a 6-month to 9-month trial of lifestyle modification fails and the patient is aged ≥10 years, consider implementing lipid-lowering therapy after consulting a lipid specialist.
  - Statin therapy should be considered for patients with elevated LDL-C levels. NHLBI provides recommendations for statin therapy in patients with specific LDL-C levels and risk factors.

### Monitoring

- Adolescents and Adults: Obtain FLP (TC, HDL-C, non-HDL-C, LDL-C, and TG) twice (>2 weeks but ≤3 months apart, average these results) Monitor FLP every 6 months (for abnormal results) or every 12 months (for normal results).
- Children (Aged ≥2 Years) without Lipid Abnormalities or Additional Risk Factors: Obtain nonfasting screening lipid profiles at entry into care and then every 6–12 months, depending on the results. If TG or LDL-C is elevated or if a patient has additional risk factors, obtain FLP.
- Children with Lipid Abnormalities and/or Additional Risk Factors: Obtain 12-hour FLP before initiating or changing therapy and every 6 months thereafter (more often if indicated).
- Children Receiving Lipid-Lowering Therapy with Statins or Fibrates: Obtain 12-hour FLP, LFT, and CK at 4 weeks, 8 weeks, and 3 months after starting lipid therapy.

<tbody>
<tr>
<td>Dyslipidemia, continued</td>
<td></td>
<td></td>
<td></td>
<td>• If there are minimal alterations in AST, ALT, and CK, monitor every 3–4 months during the first year and every 6 months thereafter (or as clinically indicated).</td>
<td>• Repeat FLP 4 weeks after increasing doses of antihyperlipidemic agents.</td>
<td>• Drug therapy can be considered in cases of severe hypertriglyceridemia (TG ≥500 mg/dL). Fibrates (gemfibrozil and fenofibrate) and N-3 PUFAs derived from fish oils may be used.</td>
</tr>
</tbody>
</table>

The long-term risks of lipid abnormalities in children who are receiving ART are unclear. However, persistent dyslipidemia in children may lead to premature ASCVD.

References

Key: ALT = alanine aminotransferase; ARV = antiretroviral; ASCVD = atherosclerotic cardiovascular disease; AST = aspartate aminotransferase; ATV = atazanavir; CK = creatine kinase; COBI = cobicistat; DRV = darunavir; DRV/r = darunavir/ritonavir; EFV = efavirenz; ETR = etravirine; EVG/c = elvitegravir/cobicistat; FLP = fasting lipid profile; FTC = emtricitabine; HDL-C = high-density lipoprotein cholesterol; INSTI = integrase strand transfer inhibitor; LDL-C = low-density lipoprotein cholesterol; LFT = liver function test; LPV/r = lopinavir/ritonavir; NHLBI = National Heart, Lung, and Blood Institute; NNRTI = non-nucleoside reverse transcriptase inhibitor; NRTI = nucleoside reverse transcriptase inhibitor; NVP = nevirapine; PI = protease inhibitor; PUFA = polyunsaturated fatty acid; RPV = rilpivirine; RTV = ritonavir; TAF = tenofovir alafenamide; TC = total cholesterol; TDF = tenofovir disoproxil fumarate; TG = triglycerides

a Given the burden of collecting fasting blood samples, some practitioners routinely measure cholesterol and TG from nonfasting blood samples and follow up abnormal values with a test done in the fasted state.
